Software Architecture Project: Final Report

Juhani Kataja

November 6, 2026

1 Introduction

2 Example syntax

This is **bold**, *italic*, and *emphasized* text.

An equation:

$$E = mc^2 \tag{1}$$

Inline math looks like $a^2 + b^2 = c^2$.

```
Code-like text is written here.
```

3 Guide

(Remove this at some point) The actual contents of the report depend on the framework (its purpose and techincal nature), but in general, the report should cover the following points (not necessarily in this order):

- The purpose and the domain (what to use it for?)
- overview of the main functional features (what does it do for you?) if applicable
- A technical overview (what is it?) and what kind of extension interface(s) it provides (inheritance, explicit configuration, convention over configuration)
- The qualities (-ilities) that the framework claims to support (what?) and justifications for the claims (how?)
- What is it not suited for (any inherent limitations or reported issues) - this may be challenging to research if framework documentation does not explain limitations; try to find blogs or other more professional articles/books discussing the pros and cons (be critical about the sources and try to find multiple sources corroborating the claims)

- Architectural impact - what aspect of application/system architecture is affected by using it and how? Tool support / automation provided (can be also from 3rd parties) to help application developers be more productive

4 Introduction

To help with the analysis, I decided to build a small idle-clicker game with Angular. I tried to use as many different basic web application features as possible, such as forms, and shared state between components.

5 About Angular

Angular is a popular web framework developed by Google. Web frameworks are used to help develop web applications.

Angular claims to be versatile, fully featured, AI-compatible and have good performance [1].
